“RAPTUS SABINAE?” COMPLEMENTED:
MOLECULAR GENETIC STUDIES ON A FEMALE
CALVARIUM OF THE BANDKERAMIK SETTLEMENT
OF ROVANTSI IN VOLHYNIA (UA)

ABSTRACT

A fragmented human cranial calotte was discovered in a Bandkeramik (LBK) settlement context at Rovantsi in Volhynia (UA). The female calvarium of a mature woman with an age of about 45-50 years was uncovered in the deepest part of a settlement pit. It can be dated to round about 5,250 BC. PCR-based molecular genetic analyses were successfully performed on these extremely rare skeletal remains from the Early Neolithic of Ukraine. The female family line can be assigned to haplogroup T2, in which it represents the lineage T2c1d+152. The woman was lactose intolerant, like most LBK individuals. Her hair colour was brown, and her eye colour was found to be hazel.

Keywords: ancient DNA (aDNA), human mitochondrial DNA haplogroup, DNA profiling, polymerase chain reaction (PCR), Early Neolithic, Bandkeramik (LBK), Ukraine

INTRODUCTION

In a previous volume of this journal, the female calvarium of Rovantsi was presented (Bardetskiy et al. 2017). It belongs to a mature woman with an age range of ca. 45-50 years. The missing jawbone and face of the calvarium, as well as some cut-marks, indicate that it had already undergone several post-mortem processes before it found its way into a settlement pit (Fig. 1). The fragmented skull was located about 2.6 m below ground level, in the deepest part of pit 19 north of house I, which had been dug almost 3 m into the loess (Bardetskiy et al. 2017, 239, fig. 4). Due to the calcareous soil conditions, the preservation of the bone can be characterized as very good.

Fig. 1. Rovantsi (UA). Female calvarium from pit 19

The site, which lies on a flat loess terrace upon the right bank of the Styr River, is rich in remarkable finds and can be dated to a later stage of the Želiezovce phase, i.e. to the 52nd-51st century BC. The skull fragment was found in pit 19 together with Šarka type pottery (Bardetskiy et al. 2017, 237, fig. 5; Saile et al. 2018, 30-31, fig. 4-5). Two radiocarbon dates obtained from samples of the calvarium placed its origin in the 53rd century BC (KIA-53054: 6287±29 BP; MAMS-35954: 6263±29 BP). At first sight, the dates seem to be too old. However, the discrepancy between the death of the woman and the time of the pit’s formation may be explained by a long-term ritual use of the body after the death of the person. About five generations later, the human remains were finally deposited in the settlement pit mentioned above. Taphonomic processes explain the difference between the archaeological ceramic dating and the dating of the bone determined by natural science.

Until today the skull fragment is the easternmost preserved human skeletal remain with a Bandkeramik cultural affiliation (Dębiec and Saile 2015). The dimensions of the robust skull differ from the expected values of the more gracile LBK average (Bardetskiy
et al. 2017, 246-250). May this be understood as a reference to a Mesolithic background of the person? Since immigrant LBK settlers introduced agriculture, cattle breeding and a sedentary way of life not only in Central Europe but also in the landscapes northeast of the Carpathians, the question of their relationship to the Mesolithic population may claim special interest.

So far, analyses of ancient DNA from numerous human skeletal finds of the LBK have resulted in the identification of genetic features of the Early Neolithic. These characteristics range from phenotypic to metabolic traits as well as maternal and paternal haplotype distributions, which among other things confirms the hypothesis of immigration from the Near East to Central Europe (Haak et al. 2010; Brandt et al. 2013; Mathieson et al. 2015). The very good bone preservation of the Rovantsi find made successful DNA analyses appear possible. Therefore, genetic analyses based on polymerase chain reaction (PCR) and a genome-wide assessment of single nucleotide polymorphisms (SNPs) were performed. We believe that the results obtained should be of interest to those studying the Early Neolithic of East Central Europe.

**SAMPLE PREPARATION, DNA EXTRACTION AND ANALYSES**

The genetic analyses were performed on the left petrous bone of the *calvarium*. For this purpose, a small piece weighing less than one gram was cut out from the cranial rim of the *pars petrosa ossis temporalis*.

To remove any possibly adhering modern DNA, the sample was immersed in a 6% NaClO solution (sodium hypochlorite) for 5 min., then rinsed in bi-distilled water for 15 min. and dried overnight at room temperature. The sample was then ground to a fine powder for 20 s at 24 Hz. in a ball triturator (MM200, Retsch®). The following preparation and all steps of the analysis were carried out repeatedly to ensure the reproducibility of the results.

Four aliquots of 0.25 g each of the powder were incubated in 3900 µl EDTA (0.5 M, pH 8.3) including 100 µl of Proteinase K for 18 h in order to chemically dissolve the inorganic apatite component of the bone powder and to break down the protein backbone of the bone cells and their nuclei. The subsequent steps of DNA isolation and purification were conducted following a standard protocol (Frischalowski et al. 2015; Flux et al. 2017). This protocol starts with an organic extraction using phenol and chloroform and is continued in the QIAvac extraction system (Qiagen®) using MinElute® columns in order to separate the DNA molecules and to reduce the finale volume of the extract to 50 µl.

A PCR approach was chosen for the analysis of the regional origin of the maternal lineage, the investigation of the lactase persistence, and the proof of authenticity of the ancient DNA through short tandem repeat (STR) typing (Hummel 2003; Butler 2015). All PCRs were done from two to four DNA extracts. The reagent mixtures and amplification proce-
Ancient DNA Authentication

The STR typing, also known as genetic fingerprinting, was performed using a mini STR heptaplex kit (Seidenberg et al. 2012), including six highly polymorphic markers and the amelogenin gene indicating biological sex (Table 1). Due to the unique combination of alleles in the bi-allelic markers, proof of authenticity of the ancient DNA was also achieved.

Moreover, the results of STR typing already indicated that the DNA showed the characteristic signs of degradation. In the agarose gel electrophoresis of the STR amplification products (Fig. 2), this can be deduced from the comparatively weak signal strengths, although the allele determination of all four analytic approaches led to a complete STR typing (= “consensus” conf. Table 1). However, a closer look at the individual results also reveals typical signs of DNA degradation. While some of the single STRs (e.g. D21S11 and D5S818) occasionally show allelic dropouts, in FGA (2nd PCR conf. Table 1) even an allelic drop-in can be observed (Butler 2015). Both types of events were attributed to the presence of only small amounts of intact indigenous DNA, which is a function of the age of the skull.

Table 1. Heptaplex typing for authentication

Key: in some of the genetic markers (Amelogenin, D13S317, D18S51) only one allele occurred in the multiple amplifications, hence, the marker was considered to reveal a homozygous genotype; in other markers (D21S11, D5S818), which were considered to reveal a heterozygous genotype, occasionally allelic dropouts of one of the alleles occurred in single amplifications due to DNA degradation.
“Raptus Sabinae?” complemented: molecular genetic studies on a female *calvarium*

Two fragments of mitochondrial hypervariable regions (HVRs) were analysed to determine the maternal lineage. HVR I was studied by amplification and sequencing of a 435-base-pair (bp) fragment from extracts 1 and 2, while HVR II is represented by a 379 bp fragment amplified from all four extracts. For the Taq cycle sequencing, readily prepared kits (Big Dye® Terminator kit v1.1, Applied Biosystems®) and standard procedures were used. For both fragments, the respective amplification primers served as forward and reverse sequencing primers (e.g. Fehren-Schmitz et al. 2010; Seidenberg 2016).

The amplification and sequencing analyses were fully reproducible and enabled clear basecalls, although signs for DNA degradation (Hofreiter et al. 2001) are visible in the sequences of the HVRs (Fig. 3). Characteristic is the so-called deamination, whereby cyto-

**MATERNAL FAMILY LINEAGE**

Fig. 3. Part of the HVR II sequence. Nucleotide positions with signs of weak deamination are marked by red arrows. Characteristic are small red peaks (Thymine), which can be recognized underneath some of the large blue peaks (Cytosine). Further, two deviations from the reference sequence (rCRS) are marked with grey arrows. The deviations in the Rovantsi sample sequence belong to the polymorphisms characteristic for the Haplogroup T2c1d+152

Key: SNP Accession No. = SNPs are identified through their accession numbers in the NCBI database GeneBank; hair colour = was identified through the software “Snipper” (Philips et al. 2007); eye colour = was identified through the use of the softwares “Snipper” (Philips et al. 2007) and “Hirisplex” (Chaitanya et al. 2018); hazel = intermediate eye colour ranging from green-brown
sine nucleotides in some of the target sequences of the DNA extract are damaged and therefore misread during amplification, which in turn leads to their replacement by thymine nucleotides.

The results of the sequencing (Table 2) allow us to assign the maternal lineage to the haplogroup T2, and within this group they represent the lineage T2c1d+152.

**DIGESTION OF UNFERMENTED MILK**

The study of so-called lactase persistence, which genetically determines the ability to digest milk in adults, was carried out by amplifying a 146 bp fragment on chromosome 2, which frames the LCT-13910 locus associated with lactase persistence (Enattah et al. 2002). The respective amplification primers are designed for being introduced to an STR multiplex amplification kit, i.e. they reveal a dye labelling in one primer for fragment length analysis (Fulge 2005; Seebode 2010). The co-amplification of STRs along with the Lac-primers also ensure the proof of authenticity for the amplification of this single bi-allelic marker. The Lac-primers replace the amelogenin primers and are designed to detect a mismatch in the 3’ region of the upper primer and introduce a cleavage site for enzymatic analysis. The genotyping of the C/T-polymorphism at the LCT-13910 locus was done through an enzymatic digestion and possible cleavage by the endonuclease Hinf I. The function of the cleavage reaction is controlled through the co-digestion of one of the STRs, which is independent from the LCT-13910 locus.

The results of the analysis show that the female individual has a homozygous expression of the C allele (Fig. 4). This indicates that she was lactose intolerant, meaning that she could not digest unfermented milk or milk products.

**EYE AND HAIR COLOUR**

The SNP typing for determining hair and eye colour was carried out in a so-called high-throughput approach targeting the relevant 24 SNPs. Basically, the standard procedures as provided by the manufacturer Fluidigm® were used. This comprises a multi-step analysis, including a software-based evaluation of the SNP typing. However, the initial enrichment step had been modified by increasing the number of amplification cycles from 14 to 20 to enable the investigation of minute amounts of ancient DNA (Schmidt et al. 2020).

The analyses showed that the colour of the woman’s eyes was hazel, with the hazel usually shifting from light brown to green. In addition, the analysis of the SNPs that determine hair colour revealed a brown appearance (Table 3). Both phenotypic characteristics are consistent with each other (Söchtig et al. 2015).
Fig. 4. Electropherograms of the Rovantsi sample and two positive controls showing the results of the lactose persistence investigation. The relevant peaks are marked by red arrows (121 and 146 bp); all other peaks represent co-amplified STRs, including the TH01 locus. Lactose intolerance is indicated by the unaffected peak at 146 bp after enzymatic digestion, representing the C allele. Lactose persistence is indicated by either a fully digested PCR product (PC1, homozygous, T allele) or a partially digested PCR product (PC2, heterozygous, C and T alleles). The homozygous state of lactose persistence can be recognized through the complete disappearance of the peak from its original position at 146 bp and the appearance of a peak at 121 bp. In the heterozygous case only part of the PCR product is digested, leading to a diminished peak height at the 146 bp position (C allele) and the additional occurrence of a peak at the 121 bp position (T allele). The success of the enzymatic digestion is monitored by TH01, which is co-digested in the process and thus disappears from the electropherogram.
RESULTS AND DISCUSSION

Mitochondrial DNA haplotyping revealed the identification of lineage T2c1d+152, a subgroup of the haplogroup T2. This has a Near Eastern origin and is thought to have spread to Europe about 10,000 years ago (Pala et al. 2012; Strien 2018, 18). It is one of the most frequent haplogroups found in LBK contexts (Haak et al. 2005; Haak et al. 2010; Brandt et al. 2013). The investigations also showed that the individual was lactose intolerant, which, in contrast to today, was the common genetic disposition of European sat the time (Mathieson et al. 2015). The analysis of 24 SNPs made it possible to determine the hair colour of the woman as brown and her eye colour as hazel. Both phenotypic characteristics are mutually consistent (Söchtig et al. 2015). They are in accordance with a Near Eastern origin. These results are similar to those obtained from the majority of the aDNA data analysed so far from this time (e.g. Cerqueira et al. 2012; Deng and Xu 2018), although the phenotypic characteristics in Early Neolithic Europe appear to have shown considerable variability (Olalde et al. 2014). The findings support an assignment of the mature woman to the Bandkeramik. The robustness of the skull thus reflects the considerable morphological variability of the individuals of this culture.
